1 Fermat's Method of Infinite Descent

Suppose we have a right-angled triangle Δ with side lengths a, b, c , so that by Pythagoras we have $a^2 + b^2 = c^2$, and $\text{area}(\Delta) = \frac{1}{2}ab$.

Definition 1.1. Δ is **rational** if $a, b, c \in \mathbb{Q}$, and **primitive** if $a, b, c \in \mathbb{Z}$ coprime.

Lemma 1.2. Every primitive triangle is of the form $a = u^2 - v^2, b = 2uv, c = u^2 + v^2$ for coprime integers $u > v > 0$.

Proof. If a, b were both odd, then $a^2 + b^2 \equiv 2 \pmod{4}$, and we have no solutions for c . If a, b both even, then they are not coprime. So we may assume a is odd, b is even, c is odd.

Then $(\frac{b}{2})^2 = \frac{c+a}{2} \frac{c-a}{2}$, and the right hand side is a product of coprime positive integers. So by unique prime factorisation in the integers, $\frac{c+a}{2} = u^2, \frac{c-a}{2} = v^2$ for some coprime integers u, v . Rearranging, we have the lemma. \square

Definition 1.3. $D \in \mathbb{Q}_{>0}$ is a **congruent number** if it is the area of a rational triangle.

Note that, by scaling the triangle, it suffices to consider $D \in \mathbb{Z}_{>0}$ squarefree.

For example, $D = 5, 6$ are congruent numbers. $6 = \frac{1}{2} \cdot 3 \cdot 4$, and $3^2 + 4^2 = 5^2$, and 5 is left as an exercise.

Lemma 1.4. $D \in \mathbb{Q}_{>0}$ is congruent if and only if $Dy^2 = x^3 - x$ for some $x, y \in \mathbb{Q}, y \neq 0$.

Proof. Lemma 1.2 shows that D is congruent if and only if $Dw^2 = uv(u^2 - v^2)$ for some $u, v, w \in \mathbb{Q}, w \neq 0$.

Setting $x = \frac{u}{v}, y = \frac{w}{v^2}$ finishes the proof. \square

Fermat showed that 1 is not a congruent number.

Theorem 1.5. There is no solution to

$$w^2 = uv(u+v)(u-v) \quad (*)$$

in integers u, v, w with $w \neq 0$.

Proof. Without loss of generality, u, v are coprime with $u > 0, w > 0$. If $v < 0$ then replace (u, v, w) by $(-v, u, w)$. If u, v are both odd, then replace (u, v, w) by $(\frac{u+v}{2}, \frac{u-v}{2}, \frac{w}{2})$. So we may assume that all of $u, v, u+v, u-v$ are coprime positive integers whose product is a square, and hence are all squares, say a^2, b^2, c^2, d^2 respectively, where $a, b, c, d \in \mathbb{Z}_{>0}$.

Since $u \not\equiv v \pmod{2}$, both c, d are odd. Consider the right angled triangle with side lengths, $\frac{c+d}{2}, \frac{c-d}{2}, a$. This is a primitive triangle, and it has area $\frac{c^2-d^2}{8} = \frac{v}{4} = (\frac{b}{2})^2$.

Let $w_1 = \frac{b}{2}$. Then lemma 1.2 gives $w_1^2 = u_1 v_1 (u_1^2 - v_1^2)$ for some $u_1, v_1 \in \mathbb{Z}$, giving a new solution to $(*)$. But $4w_1^2 = b^2 = v|w|^2$, and so $w_1 \leq \frac{1}{2}w$.

So by Fermat's method of infinite descent, if there were a solution we would have a strictly decreasing infinite sequence of positive integers $\frac{1}{2}$. Hence there is no solution to $(*)$. \square

1.1 A Variant for Polynomials

Here, K is a field with $\text{char } K \neq 2$. The algebraic closure of K will be \overline{K} .

Lemma 1.6. *Let $u, v \in K[t]$ be coprime. If $\alpha u + \beta v$ is a square for four distinct $(\alpha : \beta) \in \mathbb{P}^1$, then $u, v \in K$.*

Proof. Without loss of generality we may assume $K = \overline{K}$, as that doesn't change the degree of polynomials, and every square is still a square.

Changing coordinates on \mathbb{P}^1 , we may assume the ratios $\alpha : \beta$ are $(1 : 0), (0 : 1), (1 : -1), (1 : -\lambda)$ for some $\lambda \in K \setminus \{0, 1\}$, with $\mu = \sqrt{\lambda}$.

Then $u = a^2, v = b^2, u - v = (a + b)(a - b), u - \lambda v = (a + \mu b)(a - \mu b)$ are all squares. They are also coprime, and so by unique factorisation in $K[t]$, $(a + b), (a - b), (a + \mu b), (a - \mu b)$ are all squares.

But $\max\{\deg a, \deg b\} \leq \frac{1}{2} \max\{\deg u, \deg v\}$. So by Fermat's method of infinite descent, we get that the original $u, v \in K$. \square

Now we have some important definitions:

Definition 1.7.

1. An **elliptic curve** E over a field K is the projective closure of the affine curve $y^2 = f(x)$ where $f \in K[x]$ is a monic cubic polynomial with distinct roots.
2. For L/K any field extension, $E(L) = \{(x, y) \in L^2 : y^2 = f(x)\} \cup \{0\}$. 0 is called the **point at infinity**.

We call the point at infinity 0 because we will see that $E(L)$ is naturally an abelian group under an operation we will denote by $+$, and 0 will be the identity for that group. In this course we will study $E(L)$ for L a finite field, a local field, and a number field.

Lemma 1.4 and theorem 1.5 together imply that, if E is given by $y^2 = x^3 - x$, then $E(\mathbb{Q}) = \{0, (0, 0), (\pm 1, 0)\}$, which we will see is the group $C_2 \times C_2$.

Corollary 1.8. *Let E/K be an elliptic curve. Then $E(K(t)) = E(K)$.*

Proof. Without loss of generality, $K = \overline{K}$. By a change of coordinates we may assume $E : y^2 = x(x - 1)(x - \lambda)$ for some $\lambda \in K \setminus \{0, 1\}$. Suppose $(x, y) \in E(K(t))$. Write $x = \frac{u}{v}$ with $u, v \in K[t]$ coprime. Then $w^2 = uv(u - v)(u - \lambda v)$ for some $w \in K[t]$.

Unique factorisation in $K[t]$ gives $u, v, u - v, u - \lambda v$ are all squares, and so by lemma 1.6, $u, v \in K$, and so $x, y \in K$. \square

2 Some Remarks on Algebraic Curves

We will be working over an algebraically closed field K .

Definition 2.1. *An (irreducible) plane algebraic curve $C = \{f(x, y) = 0\} \subset \mathbb{A}^2$ is **rational** if it has a rational parametrization, i.e. there are $\phi, \psi \in K(t)$ such that:*

1. $\mathbb{A}^1 \rightarrow \mathbb{A}^2; t \mapsto (\phi(t), \psi(t))$ is injective on $\mathbb{A}^1 \setminus \{\text{finite set}\}$.
2. $f(\phi(t), \psi(t)) = 0$.

Examples 2.2.

1. Any nonsingular plane conic is rational. For example, take a circle $x^2 + y^2 = 1$. Pick a point on it, $(-1, 0)$. Now draw a line through it with slope t , and solve for the points of intersection between the curve and the line.

Solving for the coordinates of p , we get the quadratic $x^2 + t^2(x + 1)^2 = 1$, i.e. $x = -1$ or $\frac{1-t^2}{1+t^2}$. So we have the rational parametrization $(x, y) = \left(\frac{1-t^2}{1+t^2}, \frac{2t}{1+t^2}\right)$

2. Any singular plane cubic is rational.

(a) Rational Parametrization $(x, y) = (t^2, t^3)$

(b) Left as an example on the first sheet

3. Corollary 1.8 shows that elliptic curves are *not* rational.

Definition 2.3. The **genus** $g(C) \in \mathbb{Z}_{\geq 0}$ is an invariant of a smooth projective curve.

- If $K = \mathbb{C}$, then $g(C) = \text{genus of the Riemann surface } C$.

- A smooth plane curve $C \subset \mathbb{P}^2$ of degree d has genus $g(C) = \frac{(d-1)(d-2)}{2}$.

Proposition 2.4. Let C be a smooth projective curve over K , an algebraically closed field. Then:

1. C is rational $\iff g(C) = 0$.
2. C is an elliptic curve $\iff g(C) = 1$.

Proof. A proof of 1 is omitted from this course. For 2, we check (on the first example sheet) that elliptic curves are smooth plane curves. Then they have degree 3, so genus $\frac{2 \cdot 1}{2} = 1$. For the other direction, see later on in the course. \square

2.1 Order of Vanishing

C will be an algebraic curve, and $K(C)$ its function field, with $P \in C$ a smooth point. Write $\text{ord}_P(f)$ to mean the order of vanishing of $f \in K(C)$ at P (negative if f has a pole).

Fact: $\text{ord}_P : K(C)^\times \rightarrow \mathbb{Z}$ is a discrete valuation, i.e. $\text{ord}_P(f_1 f_2) = \text{ord}_P(f_1) + \text{ord}_P(f_2)$ and $\text{ord}_P(f_1 + f_2) \geq \min\{\text{ord}_P(f_1), \text{ord}_P(f_2)\}$.

We say $t \in K(C)^\times$ is a **uniformizer** at the point P if $\text{ord}_P(t) = 1$.

Example 2.5. Let $C = \{g(x, y) = 0\} \subseteq \mathbb{A}^2$, where $g \in K[x, y]$ is irreducible. Then $K(C) = \text{Frac} \frac{K[x, y]}{(g)}$, with $g = g_0 + g_1(x, y) + g_2(x, y) + \dots$, g_i homogeneous of degree i .

Suppose $P = (0, 0) \in C$ is a smooth point, i.e. $g_0 = 0, g_1(x, y) = \alpha x + \beta y$ with α, β not both zero.

Let $\gamma, \delta \in K$. It is a fact that $\gamma x + \delta y \in K(C)$ is a uniformizer at P if and only if $\frac{\gamma}{\delta} \neq \frac{\alpha}{\beta}$, i.e. $\alpha\delta - \beta\gamma \neq 0$.

Example 2.6. $\{y^2 = x(x-1)(x-\lambda)\} \subset \mathbb{A}^2$, $\lambda \neq 0, 1$. We take the projective closure, i.e. homogenize the equation as $\{Y^2 Z = X(X-Z)(X-\lambda Z)\} \subset \mathbb{P}^2$ by setting $x = X/Z, y = Y/Z$.

Have we got new points by taking projective closure? We only get these when $Z = 0$, i.e. $0 = X^3 \implies X = 0, Y \neq 0$. Since we're in projective space, this is just one point: $P = (0 : 1 : 0)$. We compute $\text{ord}_P(x)$ and $\text{ord}_P(y)$. Put $t = X/Y, w = Z/Y$ (since we can't return to the original affine piece, as it doesn't contain $Z = 0$). Then we get $w = t(t-w)(t-\lambda w)$. Now P is the point $(t, w) = (0, 0)$. This is a smooth point, as there are linear terms at that point (namely w). So $\text{ord}_P(t) = \text{ord}_P(t-2) = \text{ord}_P(t-\lambda w) = 1$, and $\text{ord}_P(w) = 1 + 1 + 1 = 3$.

Then:

$$\begin{aligned}\text{ord}_P(x) &= \text{ord}_P(X/Z) = \text{ord}_P(t/w) = 1 - 3 = -2 \\ \text{ord}_P(y) &= \text{ord}_P(Y/Z) = \text{ord}_P(1/w) = -3\end{aligned}$$

2.2 Riemann-Roch Spaces

Let C be a smooth projective curve. Then a **divisor** is a formal sum of points on C , say $D = \sum_{P \in C} n_P P$ where $n_P \in \mathbb{Z}$, and only finitely many n_P are nonzero, and let $\deg D = \sum_{P \in C} n_P$. These divisors form a group under addition, denoted $\text{Div}(C)$.

D is said to be **effective**, written $D \geq 0$ if $n_P \geq 0$ for all $P \in C$.

If $f \in K(C)^\times$, we write $\operatorname{div}(f) = \sum_{P \in C} \operatorname{ord}_P(f)P$.

The Riemann Roch space of $D \in \operatorname{Div}(C)$ is:

$$\mathcal{L}(D) = \{f \in K(C) : \operatorname{div}(f) + D \geq 0\} \cup \{0\}$$

i.e. the K -vector space of rational functions on C with “poles no worse than specified by D .”

Theorem 2.7 (Riemann Roch for genus 1).

$$\dim \mathcal{L}(D) = \begin{cases} 0 & \deg D < 0 \\ 0 \text{ or } 1 & \deg D = 0 \\ \deg D & \deg D > 0 \end{cases}$$

Example 2.6 (revisited). Our curve is $\{y^2 = x(x-1)(x-\lambda)\} \subset \mathbb{A}^2$, together with $P = (0 : 1 : 0)$, the point at infinity. Recall $\operatorname{ord}_P(x) = -2, \operatorname{ord}_P(y) = -3$.

We thus deduce that $\mathcal{L}(2P) = \langle 1, x \rangle, \mathcal{L}(3P) = \langle 1, x, y \rangle$.

Proposition 2.8. *Let K be an algebraically closed field not of characteristic 2. Let $C \subset \mathbb{P}^2$ be a smooth plane cubic, and that $P \in C$ is a point of inflection. Then we may change coordinates such that:*

$$\begin{aligned} C : Y^2Z &= X(X-Z)(X-\lambda Z), \quad \lambda \neq 0, 1 \\ P &= (0 : 1 : 0) \end{aligned}$$

Proof. We make a change of coordinates such that $P = (0 : 1 : 0)$ and the tangent line to C at P , $T_P(C) = \{Z = 0\}$. Now let $C = \{F(X, Y, Z) = 0\}$.

Since $P \in C$ is a point of inflection, $F(t, 1, 0)$ has a triple root at $t = 0$. But F is degree 3, so we have $F(t, 1, 0) = kt^3$ for k some constant. I.e., there are no terms in F of the form X^2Y, XY^2, Y^3 .

So $F \in \langle Y^2Z, XYZ, YZ^2, X^3, X^2Z, XZ^2, Z^3 \rangle$. The coefficient of Y^2Z is nonzero, as otherwise P would be singular. The coefficient of X^3 is also nonzero, as C is irreducible and otherwise $\{Z = 0\} \subset C$.

We are free to rescale X, Y, Z, F , and so WLOG C is defined by

$$Y^2Z + a_1XYZ + a_3YZ^2 = X^3 + a_2X^2Z + a_4XZ^2 + a_6Z^3$$

. We call this Weierstrass form.

Since our field doesn't have characteristic 2, we may complete the square by substituting $Y = Y - \frac{1}{2}a_1X - \frac{1}{2}a_3Z$, we may assume $a_1 = a_3 = 0$.

Now $C : Y^2Z = Z^3f(X/Z)$, where f is a monic cubic polynomial. Since C is smooth, f has distinct roots, which are WLOG $0, 1, \lambda$. So

$$C : Y^2Z = X(X-Z)(X-\lambda Z)$$

, which we call the Legendre form. □

It may be shown that the points of inflection on $C = \{F = 0\} \subset \mathbb{P}^2$ are given by $F = \det \left(\frac{\partial^2 f}{\partial X_i \partial X_j} \right) = 0$

2.3 The Degree of a Morphism

Let $\phi : C_1 \rightarrow C_2$ be a nonconstant morphism of smooth projective curves. Let $\phi^* : K(C_2) \rightarrow K(C_1)$, $f \mapsto f \circ \phi$.

Definition.

1. $\deg \phi = [K(C_1) : \phi^* K(C_2)]$
2. ϕ is separable if $K(C_1)/\phi^* K(C_2)$ is a separable field extension (which by Galois theory is automatic if $\text{char } K = 0$)

Suppose $P \in C_1, Q \in C_2, \phi : P \rightarrow Q$. Let $t \in K(C_2)$ be a uniformizer at Q . We then define $e_\phi(P) = \text{ord}_P(\phi^* t)$, which is always ≥ 1 , and independent of t . $e_\phi(P)$ is called the **ramification index** of ϕ at P .

Theorem 2.9. Let $\phi : C_1 \rightarrow C_2$ be a nonconstant morphism of smooth projective curves. Then

$$\sum_{P \in \phi^{-1}(Q)} e_\phi(P) = \deg \phi$$

for any point $Q \in C_2$. Moreover, if ϕ is separable then $e_\phi(P) = 1$ with at most finitely many exceptions.

In particular:

1. ϕ is surjective
2. If ϕ is separable, $\#\phi^{-1}(Q) \leq \deg \phi$, with equality for all but finitely many choices of Q .

Remark 2.10. Let C be an algebraic curve. A rational map is given by $\phi : C \dashrightarrow \mathbb{P}^n, P \mapsto (f_0(P) : \dots : f_n(P))$, where $f_0, \dots, f_n \in K(C)$ are not all zero. If C is smooth then ϕ is a morphism.

3 Weierstrass Equations

In this section, K is a perfect field (so that all finite extensions of K are separable), with algebraic closure \bar{K} .

Definition. An elliptic curve E over K is a smooth projective curve of genus 1 defined over K with a specified K -rational point O_E .

Example: Take $\{X^3 + pY^3 + p^2Z^3 = 0\} \subset \mathbb{P}^2$ for p prime. This is not an elliptic curve over \mathbb{Q} since there is no \mathbb{Q} -points.

Theorem 3.1. Every elliptic curve E is isomorphic over K to a curve in Weierstrass form via an isomorphism taking O_E to $(0 : 1 : 0)$.

Proposition 2.8 treated the special case where E is a smooth plane cubic and O_E is a point of inflection.

If $D \in \text{Div}(E)$ is defined over K (i.e. fixed by the natural action of $\text{Gal}(\bar{K}/K)$), then $\mathcal{L}(D)$ has a basis in $K(E)$, not just in $\bar{K}(E)$.

Proof. Note that

$$\mathcal{L}(2O_E) \subset \mathcal{L}(3O_E)$$

Pick bases of these spaces, say $\{1, x\}$ and $\{1, x, y\}$.

Note that $\text{ord}_{O_E}(x) = -2, \text{ord}_{O_E}(y) = -3$. The 7 elements $\{1, x, y, x^2, xy, x^3, y^2\}$ are rational functions with no pole except at O_E , where they have poles of degree at most 6, so they all lie in $\mathcal{L}(6O_E)$. Riemann-Roch tells us this space has dimension 6, so there is a dependence relation between these elements.

Leaving out x^3 or y^2 gives a basis for $\mathcal{L}(6O_E)$ since each term has a different order pole at O_E , so they are independent.

Therefore this dependence relation *must* involve both x^3 and y^2 . Rescaling x, y we get

$$y^2 + a_1xy + a_3y = x^3 + a_2x^2 + a_4x + a_6$$

Let E' be the curve defined by this equation (or rather its projective closure).

There is a morphism

$$\phi : E \rightarrow E'$$

$$P \mapsto (x(P) : y(P) : 1) = \left(\frac{x}{y}(P) : 1 : \frac{1}{y}(P) \right)$$

$$O_E \mapsto (0 : 1 : 0)$$

$$[K(E) : K(x)] = \deg(E \xrightarrow{x} \mathbb{P}^1) = \text{ord}_{O_E}\left(\frac{1}{x}\right) = 2$$

$$[K(E) : K(y)] = \deg(E \xrightarrow{y} \mathbb{P}^1) = \text{ord}_{O_E}\left(\frac{1}{y}\right) = 3$$

This gives us a diagram of field extensions

So $[K(E) : K(x, y)]$ divides both 2 and 3 by the tower law, and hence $K(E) = K(x, y)$, and hence $\deg(E \xrightarrow{\phi} E') = 1$, and ϕ is birational. If E' is singular, then it is rational, and so E is also rational \nmid . So E' is not singular and hence smooth, and we may use remark **2.10** to ϕ^{-1} to see that ϕ^{-1} is a morphism, and hence ϕ is an isomorphism. \square

Proposition 3.2. *Let E, E' be elliptic curves over K in Weierstrass form. Then $E \cong E'$ over K if and only if the Weierstrass equations are related by a change of variables of the form*

$$\begin{aligned} x &= u^2x' + r \\ y &= u^3yu' + u^2sx' + t \end{aligned}$$

for $u, r, s, t \in K, u \neq 0$.

Proof. Using the notation of the previous proof,

$$\begin{aligned}\langle 1, x \rangle &= \mathcal{L}(2O_E) = \langle 1, x' \rangle \\ \langle 1, x, y \rangle &= \mathcal{L}(3O_E) = \langle 1, x', y' \rangle \\ \implies &\begin{cases} x = \lambda x' + r & \lambda_1 r \in K, \lambda \neq 0 \\ y = \mu y' + \sigma x' + t & \mu, \sigma, t \in K, \mu \neq 0 \end{cases}\end{aligned}$$

Looking at the coefficients of x^3 and y^2 , $\lambda^3 = \mu^2 \implies (\lambda, \mu) = (u^2, u^3)$ for $u \in K^\times$.

Put $s = \sigma/u^2$ □

The effect of this transformation on the coefficients a_i is on the formula sheet for this course. A Weierstrass equation defines an elliptic curve if and only if it defines a smooth curve, if and only if $\Delta(a_1, \dots, a_6) \neq 0$ where Δ is as follows:

$$\begin{aligned}b_2 &:= a_1^2 + 4a_2 \\ b_4 &:= 2a_4 + a_1a_3 \\ b_6 &:= a_3^2 + 4a_6 \\ b_8 &:= a_1^2a_6 + 4a_2a_6 - a_1a_3a_4 + a_2a_3^2 - a_4^2 \\ \Delta &:= -b_2^2b_8 - 8b_4^3 - 27b_6^2 + 9b_2b_4b_6\end{aligned}$$

If $\text{char } K \neq 2, 3$, then we can reduce to the case

$$\begin{aligned}E : y^2 &= x^3 + ax + b \\ \Delta &= -16(4a^3 + 27b^2)\end{aligned}$$

Corollary 3.3. Assume $\text{char } K \neq 2, 3$. If we have two elliptic curves

$$\begin{aligned}E : y^2 &= x^3 + ax + b \\ E' : y^2 &= x^3 + a'x + b'\end{aligned}$$

then they are isomorphic over K if and only if

$$\begin{aligned}a' &= u^4a \\ b' &= u^6b\end{aligned}$$

for some $u \in K^\times$.

Proof. E and E' are related as in **3.2** with $r = s = t = 0$. □

Definition. The ***j*-invariant** is $j(E) = \frac{1728(4a^3)}{4a^3 + 27b^2}$. Note that the denominator is nonzero since the discriminant is nonzero.

Corollary 3.4. $E \cong E' \implies j(E) = j(E')$, and the converse holds if $K = \bar{K}$.

Proof.

$$\begin{aligned}E \cong E' &\iff a' = u^4a; b' = u^6b \text{ for some } u \in K^\times \\ &\implies (a^3 : b^2) = ((a')^3 : (b')^2) \\ &\iff j(E) = j(E')\end{aligned}$$

and the reverse implication holds in the second line if $K = \bar{K}$. □

4 Group Law

Let $E \subset \mathbb{P}^2$ be a smooth plane cubic, and $O_E \in E(K)$. Since E is of degree 3, it meets each line in 3 points counted with multiplicity. Hence, given two points P, Q on E , the line \overline{PQ} meets E at a third point S . Then the line $\overline{O_E S}$ meets E at a third point R . We then define $P \oplus Q = R$.

If $P = Q$, then we take the tangent line at P , likewise if $S = O_E$. We can view this diagrammatically as follows:

Figure 2: Illustration of the group operation on an elliptic curve

We call this the “chord and tangent process”.

Theorem 4.1. (E, \oplus) is an abelian group.

Proof.

- (i) $P \oplus Q = Q \oplus P$ by construction.
- (ii) O_E is the identity.
- (iii) For inverses, let S be the third point of intersection of T_{O_E} and E , and Q be the third point of intersection of \overline{PS} and E . Then $P \oplus Q = O_E$.
- (iv) Associativity is much harder.

□

Definition. $D_1, D_2 \in \text{Div}(E)$ are **linearly equivalent** (written $D_1 \sim D_2$) if there is $f \in \bar{K}(E)^\times$ such that $\text{div}(f) = D_1 - D_2$. Then we will let $[D] = \{D' : D' \sim D\}$.

Definition. The **Picard group of E** , $\text{Pic}(E) = \text{Div}(E) / \sim$. We write $\text{Div}^0(E) := \ker \left(\text{Div}(E) \xrightarrow{\deg} \mathbb{Z} \right)$ for the group of degree 0 divisors on E , and then $\text{Pic}^0(E) = \text{Div}^0(E) / \sim$. Sometimes Pic^0 is called the Jacobian.

Proposition 4.2. Let $\psi : E \rightarrow \text{Pic}^0(E); P \mapsto [(P) - (O_E)]$. Then:

1. $\psi(P \oplus Q) = \psi(P) + \psi(Q)$
2. ψ is a bijection

Proof.

1. Referring back to Fig. 2, let $\{\ell = 0\}$ be the line \overline{PQ} , and $\{m = 0\}$ be the line $\overline{O_E R}$. Then:

$$\begin{aligned}
\operatorname{div}(\ell/m) &= (P) + (S) + (Q) - (R) - (S) - (O_E) \\
&= (P) + (Q) - (O_E) - (P \oplus Q) \\
\implies (P \oplus Q) + (O_E) &\sim (P) + (Q) \\
\implies (P \oplus Q) - (O_E) &\sim (P) - (O_E) + (Q) - (O_E) \\
\implies \psi(P \oplus Q) &= \psi(P) + \psi(Q)
\end{aligned}$$

2. For injectivity, suppose $\psi(P) = \psi(Q)$. Then there is $f \in \bar{K}(E)^\times$ such that $\operatorname{div}(f) = P - Q$. Then $\deg \left(E \xrightarrow{f} \mathbb{P}^1 \right) = \operatorname{ord}_P(f) = 1$. But then f is a birational morphism, so an isomorphism, and $E \cong \mathbb{P}^1$.

For surjectivity, let $[D] \in \operatorname{Pic}^0(E)$. Then $D + (O_E)$ has degree 1 (as D had degree 0). Then Riemann-Roch tells us $\dim \mathcal{L}(D + (O_E)) = 1$, and so there exists some $f \in \bar{K}(E)^\times$ such that $\operatorname{div}(f) + D + (O_E) \geq 0$. Since f is rational, $\deg \operatorname{div}(f) = 0$, and $\deg D = 0$. So the coefficients of $\operatorname{div}(f) + D + (O_E)$ are non-negative and sum to 1, hence one of them is 1 and the rest are 0. So $\operatorname{div}(f) + D + (O_E) = (P)$ for some $P \in E$. But then $(P) - (O_E) \sim D$, i.e. $\psi(P) = [D]$.

□

So ψ is a bijection respecting the group law, and so we deduce that \oplus is associative, and then $(E, \oplus) \stackrel{\psi}{\cong} (\operatorname{Pic}^0 E, +)$.
